

# GAS ANALYSERS FOR CCS, DAC, AND E-FUELS

Carbon capture is the foundation of carbon dioxide (CO<sub>2</sub>) capture and storage, or utilisation. Capturing CO<sub>2</sub> from a flue gas stream often relies on a solvent or solid adsorbent material that is sensitive to other chemicals in the raw flue gas such as sulphur dioxide (SO<sub>2</sub>). So, the CO<sub>2</sub> separation, or capture, is often the last stage in a complex arrangement of flue gas treatment (FGT).

Measurement and control of the CO<sub>2</sub> purity through the MCCUS process and the analysis of critical impurities relies on gas analysis instrumentation. Some of the gas analysers are like those that have been used in continuous emissions monitoring (CEM) for decades. However, the measurement of CO<sub>2</sub> purity is an emerging requirement.

Much of the CO<sub>2</sub> captured from industrial processes today relies on a liquid amine solvent. It is a twin tower process where CO<sub>2</sub> from the flue gas is absorbed into the solvent in the first tower. The CO<sub>2</sub>-lean flue gas then flows to atmosphere.

The CO<sub>2</sub>-rich amine is pumped to a second tower where heat is used to strip the CO<sub>2</sub> out of the amine solvent. The regenerated, CO<sub>2</sub>-lean amine solvent is pumped back to the absorber tower to collect more CO<sub>2</sub> and the process operates continuously with the solvent being recirculated from the absorber to the stripper.

Over time, the amine solvent is degraded through reactions with oxygen and other impurities in the flue gas. It is particularly sensitive to sulphur compounds such as sulphur dioxide (SO<sub>2</sub>) and the flue gas from coal or heavy fuel oil combustion will contain a high level of SO<sub>2</sub>.

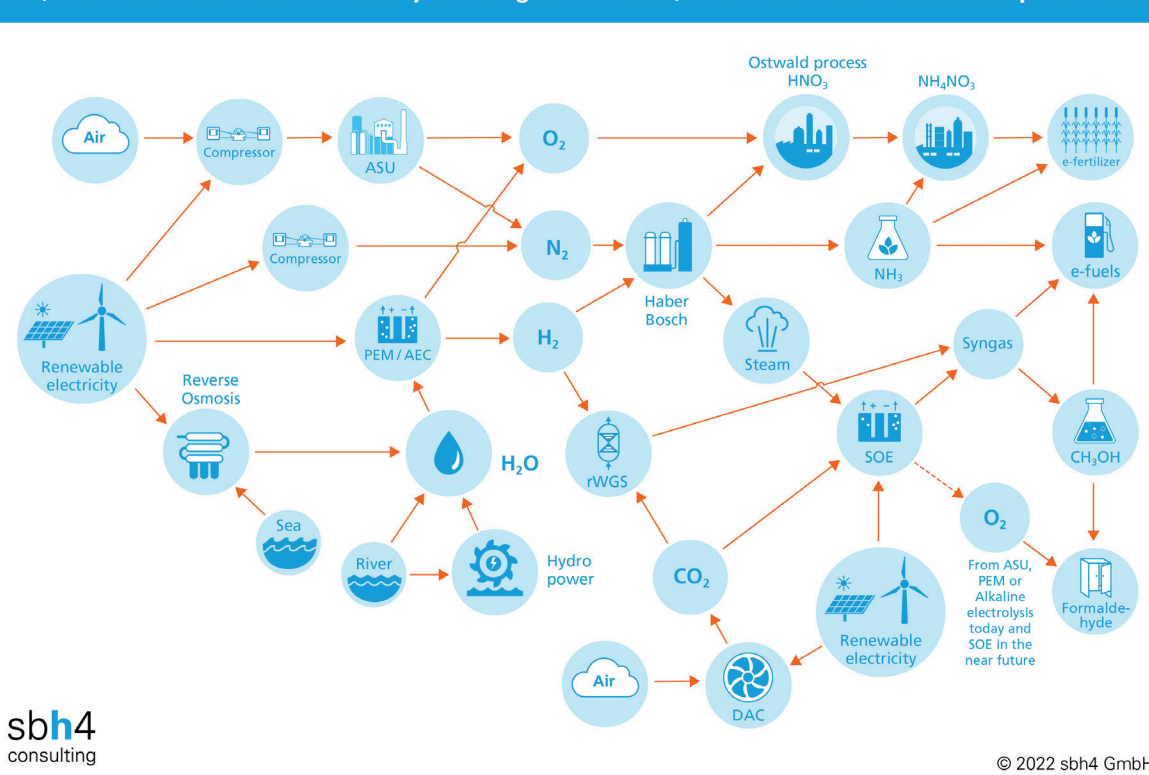

Removal of SO<sub>2</sub> is already implemented on many combustion plants in developed nations, to avoid the problem of acid rain. However, flue gas desulphurisation (FGD) is not universal, and it is only recently that developing nations such as China and India have implemented regulations to ensure that SO<sub>2</sub> emissions are reduced. It is likely that for some operators, implementation of CO<sub>2</sub> capture will require implementation of upstream SO<sub>2</sub> capture through FGD.

Hot/wet extractive, cold/dry extractive, and in-situ gas analysers for process control and CEM are all relevant for these various applications.

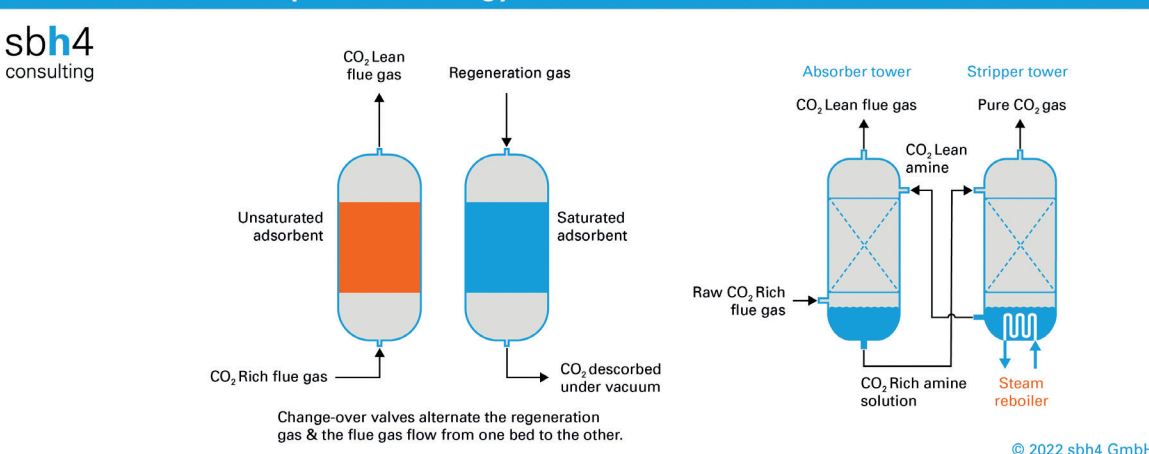

In addition to the measurement requirements between the raw flue gas and the CO<sub>2</sub> amine solvent absorption system, a CO<sub>2</sub> gas analyser in the 90 to 100% range must be used to measure the purity of the CO<sub>2</sub> liberated from the stripping tower. The CO<sub>2</sub> at this point in the process will be saturated with moisture. This must be monitored to control downstream processes such as CO<sub>2</sub> drying, liquefaction, or compression.

CO<sub>2</sub> can be purified and liquefied for transportation by road to other commercial utilisation applications. Prior to liquefaction, the CO<sub>2</sub> is dried on a regenerative dryer bed to avoid moisture

## Air, water and renewable electricity for integrated e-fuels, e-fertilizers and e-chemicals production

## Established Carbon Capture Technology – VSA and Amine Solvent

	VSA – vacuum swing adsorption	Amine Solvent with tower contactors
Separation principle	Adsorption	Absorption
Specific energy demand	1.7 GJ/t <sub>CO2</sub> (mostly power)	3 GJ/t <sub>CO2</sub> (mostly heat from steam)
Typical temperature	40°C	40-60°C in absorber, 120°C in stripper
Typical pressure	Cycling between moderate pressure and vacuum	Ambient to 30 bar
Typical CO <sub>2</sub> removal	< 90 %	> 90 %
Typical CO <sub>2</sub> purity	< 95 %	> 99 %
Typical plant size (tonnes per year CO <sub>2</sub> removal)	> 1,000 - 500,000	40,000 - 4,000,000
Technology maturity level	Commercial with some demonstrations, eg Air Products Port Arthur SMRs, USA	Commercial from many suppliers

freezing and blocking the cryogenic liquefaction system.

The alternative CO<sub>2</sub> transportation mode is compression to a supercritical fluid at around 90 bar and then transmission in a high-pressure steel pipeline. As with liquefaction, CO<sub>2</sub> and moisture analysis for pipeline transmission is essential. If moisture is present, it can react with CO<sub>2</sub> to form a corrosive acid which could damage the steel pipeline.

Drying takes place during the compression stages to remove the moisture. Most of the water is condensed in the intercoolers between the multiple gas compression stages. Prior to the last stage of compression, mono-ethylene glycol can be used to remove traces of moisture. Analysis of moisture and CO<sub>2</sub> at critical points in the drying process is vital.

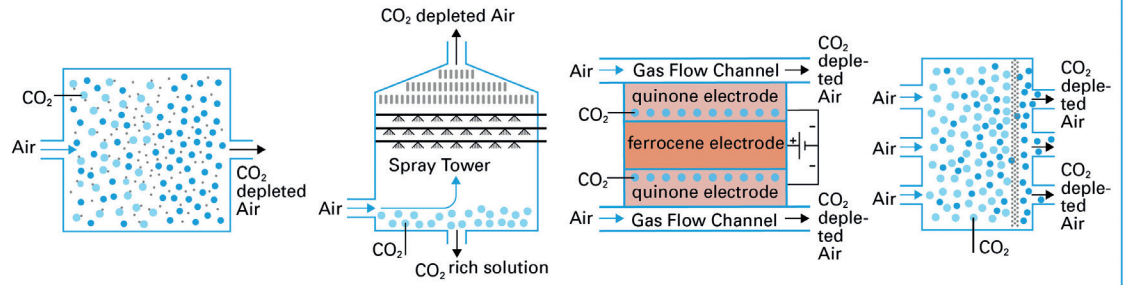

Production of e-fuels such as e-kerosene or e-methanol involves the combination of green hydrogen and CO<sub>2</sub> to build hydrocarbon molecules. The CO<sub>2</sub> can be supplied either as liquid or pipeline from captured emissions. Alternatively, CO<sub>2</sub> can be directly captured from the air.

Green hydrogen is produced in a sustainable way using renewable electrical power and electrolysis. In many cases, it is being proposed that additional renewable electricity is generated to operate a direct air capture (DAC) facility to ensure that the CO<sub>2</sub> in the e-fuels is sustainable. Monitoring of the CO<sub>2</sub> purity between the DAC unit and any downstream catalytic processes is essential to ensure that high purity CO<sub>2</sub> is used in these sensitive Fischer Tropsch, methanol synthesis and reverse water gas shift reactors.

DAC technologies for direct air capture of carbon dioxide
